orthogonalization

L. Olson

Department of Computer Science University of Illinois at Urbana-Champaign

objectives

- Understand the concepts of orthogonal and orthonormal vectors
- Know the definition of an orthogonal matrix
- Know how to construct a pair of orthogonal vectors
- Be able to implement the Gram-Schmidt algorithm
 - Gram-Schmidt orthonormalizes of a set of vectors
- Understand how to find the QR factorization of a matrix

conditioning

- We have seen A^TA used to compute the SVD of a matrix A.
 - We will see $A^TAx = A^Tb$ used to fit a line to a set of data points.
- How does the conditioning of A^TA compare to that of A?

Theorem

```
cond(A^TA) = (cond(A))^2
```

```
1 A = np.random.rand(10,10)
2 print(np.linalg.cond(A))
3 print(np.linalg.cond(A.T.dot(A)))
4 50.0972712517
5 2509.73658686
```

- What does the condition number tell us?
 - This is an issue when solving a system of equations...
- Today we will look at another matrix factorization A = QR
 - An alternative to solving the system $A^TAx = A^Tb$

other approaches

- QR factorization.
 - For $A \in \mathbb{R}^{m \times n}$, factor A = QR where
 - Q is an $m \times m$ orthogonal matrix
 - R is an $m \times n$ upper triangular matrix (since R is an $m \times n$ upper triangular matrix we can write $R = \begin{bmatrix} R' \\ 0 \end{bmatrix}$ where R is $n \times n$ upper triangular and 0 is the $(m-n) \times n$ matrix of zeros)
- SVD singular value decomposition
 - For $A \in \mathbb{R}^{m \times n}$, factor $A = USV^T$ where
 - U is an $m \times m$ orthogonal matrix
 - V is an $n \times n$ orthogonal matrix
 - S is an m × n diagonal matrix whose elements are the singular values.

и

orthogonal matrices

Definition

A matrix Q is orthogonal if

$$Q^TQ = QQ^T = I$$

Orthogonal matrices preserve the Euclidean norm of any vector v,

$$||Qv||_2^2 = (Qv)^T(Qv) = v^TQ^TQv = v^Tv = ||v||_2^2.$$

5

One way to obtain the *QR* factorization of a matrix *A* is by Gram-Schmidt orthogonalization.

We are looking for a set of orthogonal vectors q that span the range of A.

For the simple case of 2 vectors $\{a_1, a_2\}$, first normalize a_1 and obtain

$$q_1=\frac{a_1}{||a_1||}.$$

Now we need q_2 such that $q_1^T q_2 = 0$ and $q_2 = a_2 + cq_1$. That is,

$$R(q_1, q_2) = R(a_1, a_2)$$

Enforcing orthogonality gives:

$$q_1^T q_2 = 0 = q_1^T a_2 + c q_1^T q_1$$

6

$$q_1^T q_2 = 0 = q_1^T a_2 + c q_1^T q_1$$

Solving for the constant c.

$$c = -\frac{q_1^T a_2}{q_1^T q_1}$$

reformulating q_2 gives.

$$q_2 = a_2 - \frac{q_1^T a_2}{q_1^T q_1} q_1$$

Adding another vector a_3 and we have for q_3 ,

$$q_3 = a_3 - rac{q_2^T a_3}{q_2^T q_2} q_2 - rac{q_1^T a_3}{q_1^T q_1} q_1$$

Repeating this idea for n columns gives us Gram-Schmidt orthogonalization.

7

Since R is upper triangular and A = QR we have

$$a_1 = q_1 r_{11}$$

 $a_2 = q_1 r_{12} + q_2 r_{22}$
 $\vdots = \vdots$
 $a_n = q_1 r_{1n} + q_2 r_{2n} + ... + q_n r_{nn}$

From this we see that $r_{ij} = \frac{q_i^T a_j}{q_i^T q_i}$, j > i

В

```
def qr(A):

Q = np.zeros(A.shape)

for k in range(A.shape[1]):
    avec = A[:, k]

q = avec
    for j in range(k):
        q = q - np.dot(avec, Q[:,j])*Q[:,j]
```
