Suppose we seek eigenvalues $D = X^{-1}AX$, but find those of a slightly perturbed matrix $D + \delta D = \hat{X}^{-1}(A + \delta A)\hat{X}$:

Note that the eigenvalues of $X^{-1}(A + \delta A)X = D + X^{-1}\delta AX$ are also $D + \delta D$. So if we have perturbation to the matrix $||\delta A||_F$, its effect on the eigenvalues corresponds to a (non-diagonal/arbitrary) perturbation of a diagonal matrix of eigenvalues, with norm

$$||X^{-1}||_2||\delta A||_F||X||_2 = \kappa(X)||\delta A||_F.$$  

Thus it generally suffices to consider the effect of a (possibly larger) perturbation $\delta \hat{A}$ to a diagonal matrix: Given a matrix $A \in \mathbb{R}^{n \times n}$, let $r_i = \sum_{j \neq i} |a_{ij}|$. We define the Gershgorin disks as

$$D_i = \{z \in \mathbb{C} : |z - a_{ii}| \leq r_i\}.$$  

The eigenvalues $\lambda_1, \ldots, \lambda_n$ of any matrix $A \in \mathbb{R}^{n \times n}$ are contained in the union of the Gershgorin disks, $\forall i \in \{1, \ldots, n\}, \lambda_i \in \bigcup_{j=1}^n D_j$. 

>Perturbation Analysis of Eigenvalue Problems
Conditioning of Particular Eigenpairs

- Consider the effect of a matrix perturbation on an eigenvalue $\lambda$ associated with a right eigenvector $x$ and a left eigenvector $y^H$, $\lambda = y^H A x / y^H x$

For a sufficiently small perturbation $\delta A$, the change the eigenvalue $\lambda$ is perturbed to an eigenvalue $\hat{\lambda}$ of $\hat{A} = A + \delta A$,

$$\hat{\lambda} - \lambda = y^H \delta A x / y^H x \leq \frac{||\delta A||}{|y^H x|}$$

- Compare the accuracy of a Rayleigh quotient eigenvalue approximation given a normalized perturbed eigenvector (e.g. iterative guess) $\hat{x} = x + \delta x$, and an estimate that used both eigenvectors (also $\hat{y} = y + \delta y$),

$$|\hat{\lambda}_{xAx} - \lambda| \approx \delta x^H A x + x A \delta x \leq \lambda ||\delta x|| + \left( \lambda (y^H x) + (1 - y^H x) ||A|| \right) ||\delta x||$$

$$|\hat{\lambda}_{yAx} - \lambda| \approx \delta y^H A x + y^H A \delta x \leq \lambda (||\delta x|| + ||\delta y||)$$
In orthogonal iteration $\hat{Q}_{i+1} \hat{R}_{i+1} = A \hat{Q}_i$, QR iteration computes $A_{i+1} = R_i Q_i = \hat{Q}_i^T A \hat{Q}_{i+1}$ at iteration $i$:

- Using induction, assume $A_i = \hat{Q}_i^T A \hat{Q}_i$
- QR iteration finds $Q_i R_i = A_i$
- Orthogonal iteration computes

$$\hat{Q}_{i+1} \hat{R}_{i+1} = A \hat{Q}_i = \hat{Q}_i A_i = \hat{Q}_i Q_i R_i$$

and so then we have $A_{i+1} = \hat{Q}_i^T A \hat{Q}_{i+1} = \hat{R}_{i+1} \hat{Q}_i^T \hat{Q}_{i+1} = R_i Q_i$
QR Iteration with Shift

- Describe QR iteration with shifting

\[ Q_i R_i = A_i - \sigma_i I \]
\[ A_{i+1} = R_i Q_i + \sigma_i I \]

*note that \( A_{i+1} \) is similar to \( A_i \)*

- The shift is typically selected to accelerate convergence with respect to a particular eigenvalue:

*We can select the shift as the bottom right element of \( A_i \), which would be the smallest eigenvalue if \( A_i \) is triangular (we have converged). Such shifting should accelerate convergence of the last column of \( A_i \), once finished we should operate only on the first \( n - 1 \), and so on.*
Hessenberg and Tridiagonal Form

- Describe reduction to Hessenberg form

QR provides us with a way to reduce a matrix to triangular form by an orthogonal transformation. For the eigenvalue problem, we wish to perform similarity transformations, which need to be applied from both sides. Note that if simply compute the QR factorization of the first panel of $A = [A_1, A_2]$, $A_1 = QR$, then $Q^T A Q$ is still generally dense $Q^T A$ has at least as many zeros as in $R$. However, we can use QR factorization to introduce zeros by similarity transformation via

$$\begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix} = \begin{bmatrix} A_{11} & A_{12} \\ QR & A_{22} \end{bmatrix} = \begin{bmatrix} I & \quad A_{11} \\ \quad Q & \quad R \end{bmatrix} \begin{bmatrix} I & \quad A_{12}Q \\ \quad Q^T & \quad A_{22}Q \end{bmatrix} \begin{bmatrix} I \\ \quad Q^T \end{bmatrix}$$

if we pick $A_{11}$ to be $1 \times 1$ then doing this for each panel will yield an upper-Hessenberg result.

- Describe reduction to tridiagonal form in symmetric case

In the symmetric case $A_{12}Q = A_{21}^T Q = (Q^T A_{21})^T = R^T$, so we reduce to a banded (tridiagonal if $A_{11}$ is $1 \times 1$) matrix.
QR Iteration Complexity

- Compare complexity of QR iteration for various matrices

  *Reduction to upper-Hessenberg or tridiagonal in the symmetric case, cost $O(n^3)$ operations and can be done in a similar style to Householder QR.*

  *Given an upper-Hessenberg matrix,*
  
  - reduction to upper-triangular requires $n - 1$ Givens rotations,
  - computation of $RQ$ can be done by application of the $n - 1$ Givens rotations to $R$ from the right
  
  Both steps cost $O(n^2)$ computation, for $O(n^3)$ overall assuming QR iteration converges in $O(n)$ steps.

  *Given a tridiagonal matrix the same two general steps are required, but now each step costs $O(n)$, so overall the eigenvalues and eigenvectors of a tridiagonal matrix can be computed with $O(n^2)$ work.*
