Linear Least Squares

University of Illinois at Urbana-Champaign

¹*These slides have been drafted by Edgar Solomonik as lecture templates and supplementary material for the book “Scientific Computing: An Introductory Survey” by Michael T. Heath ([slides](#)).*

Linear Least Squares

- ▶ Find $\mathbf{x}^* = \operatorname{argmin}_{\mathbf{x} \in \mathbb{R}^n} \|\mathbf{Ax} - \mathbf{b}\|_2$ where $\mathbf{A} \in \mathbb{R}^{m \times n}$:

- ▶ Given the SVD $\mathbf{A} = \mathbf{U}\mathbf{\Sigma}\mathbf{V}^T$ we have $\mathbf{x}^* = \underbrace{\mathbf{V}\mathbf{\Sigma}^\dagger\mathbf{U}^T}_{\mathbf{A}^\dagger} \mathbf{b}$, where $\mathbf{\Sigma}^\dagger$ contains the reciprocal of all nonzeros in $\mathbf{\Sigma}$:

Data Fitting via Linear Least Squares

- ▶ Given a set of m points with coordinates x and y , seek an $n - 1$ degree polynomial p so that $p(x_i) \approx y_i$ by minimizing

- ▶ we can write this objective as a linear least squares problem

Conditioning of Linear Least Squares

- ▶ Consider a perturbation δb to the right-hand-side b
- ▶ The amplification in relative perturbation magnitude (from b to x) depends on how much of b is spanned by the columns of A ,

Normal Equations

Demo: Normal equations vs Pseudoinverse

Demo: Issues with the normal equations

- ▶ *Normal equations* are given by solving $A^T A x = A^T b$:

- ▶ However, solving the normal equations is a more ill-conditioned problem than the original least squares algorithm

Solving the Normal Equations

- ▶ If \mathbf{A} is full-rank, then $\mathbf{A}^T \mathbf{A}$ is symmetric positive definite (SPD):

- ▶ Since $\mathbf{A}^T \mathbf{A}$ is SPD we can use Cholesky factorization, to factorize it and solve linear systems:

QR Factorization

- ▶ If A is full-rank there exists an orthogonal matrix Q and a unique upper-triangular matrix R with a positive diagonal such that $A = QR$

- ▶ A reduced QR factorization (unique part of general QR) is defined so that $Q \in \mathbb{R}^{m \times n}$ has orthonormal columns and R is square and upper-triangular

- ▶ We can solve the normal equations (and consequently the linear least squares problem) via reduced QR as follows

Gram-Schmidt Orthogonalization

Demo: Gram-Schmidt–The Movie
Demo: Gram-Schmidt and Modified Gram-Schmidt

▶ **Classical Gram-Schmidt process for QR:**

▶ **Modified Gram-Schmidt process for QR:**

Householder QR Factorization

- ▶ A Householder transformation $Q = I - 2uu^T$ is an orthogonal matrix defined to annihilate entries of a given vector z , so $Qz = \pm\|z\|_2 e_1$:

- ▶ Imposing this form on Q leaves exactly two choices for u given z ,

$$u = \frac{z \pm \|z\|_2 e_1}{\|z \pm \|z\|_2 e_1\|_2}$$

Givens Rotations

- ▶ Householder reflectors reflect vectors, Givens rotations rotate them

- ▶ Givens rotations are defined by orthogonal matrices of the form $\begin{bmatrix} c & s \\ -s & c \end{bmatrix}$

Truncated SVD

- ▶ After floating-point rounding, rank-deficient matrices typically regain full-rank but have nonzero singular values on the order of $\epsilon_{\text{mach}}\sigma_{\text{max}}$

- ▶ By the *Eckart-Young-Mirsky theorem*, truncated SVD also provides the best low-rank approximation of a matrix (in 2-norm and Frobenius norm)
