

Review:

- Int operators

$$A_{ij} = \frac{1}{|x_i - y_j|}$$

↑ ↑
tgt src

"compact"

- LRA
↳ SVD

Goals:

- randomized LRA
- two different forms

-
- f/w

$$ABC = (AB)C = A(BC)$$

$$ABx = (AB)x = A(Bx)$$

$$\begin{aligned} (T\varphi)(x) &= \int_a^x k_1(x,y) \varphi(y) dy \\ &= \int_a^b \tilde{k}_1(x,y) \varphi(y) dy \end{aligned}$$

Eckart-Young-Mirsky Theorem

Theorem (Eckart-Young-Mirsky)

SVD $A = U\Sigma V^T$. If $k < r = \text{rank}(A)$ and

$$A_k = \sum_{i=1}^k \sigma_i u_i v_i^T,$$

then

$$\min_{\text{rank}(B)=k} \|A - B\|_2 = \|A - A_k\|_2 = \sigma_{k+1}.$$

U, V orth.
 $\Sigma = \text{diag}(\vec{\sigma})$

$$\Sigma = \begin{pmatrix} \sigma_1 & & & \\ & \ddots & & \\ & & \sigma_n & \\ & & & 0 \end{pmatrix}$$
$$\Sigma_n = \begin{pmatrix} \sigma_1 & & & \\ & \ddots & & \\ & & \sigma_n & \\ & & & 0 \end{pmatrix}$$

Q: What's that error in the Frobenius norm?

So in principle that's good news:

- ▶ We can find the numerical rank.
- ▶ We can also find a factorization that reveals that rank (!)

Demo: Rank of a Potential Evaluation Matrix (Attempt 2)

$$\min_{\text{rank}(B)=k} \|A - B\|_2 = \|A - A_k\|_2 = \sigma_{k+1}.$$

$$\min_{\text{rank}(B)=k} \|A - B\|_F = \|A - A_k\|_F =$$

$$\| \Sigma - \Sigma_k \|_F = \sqrt{\sigma_{k+1}^2 + \dots + \sigma_n^2}$$

Constructing a tool

There is still a slight downside, though.

- Forming the matrix: $O(N^2)$
- Computing the SVD: $O(N^3)$

↑
too expensive

Representation

What does all this have to do with (right-)preconditioning?

$$A \vec{u} = b$$

$$\begin{aligned} \rightarrow \Delta u &= 0 \text{ on } \Omega \\ u &= g \text{ on } \partial\Omega \end{aligned}$$

Left precondition: $M_1 A \vec{u} = M_1 b$

Right precondition: $\vec{u} = M_2 \vec{\sigma}$

$$(A M_2) \vec{\sigma} = b$$

fallt skinny

¹ right-precondition away the PDE's

Rephrasing Low-Rank Approximations

SVD answers low-rank-approximation ('LRA') question. But: too expensive. First, rephrase the LRA problem:

$$A \approx BC^T$$

↳ factorization form

$$B = \underbrace{\quad}_k \quad C = \underbrace{\quad}_k$$
$$A \approx Q \underbrace{Q^T A}_{\text{projection form}}$$

proj. → fact form?

$$Q = \underbrace{\quad}_k \text{ orth.}$$
$$A \approx \underbrace{Q}_B \underbrace{Q^T A}_C$$

Using LRA bases

If we have an LRA basis Q , can we compute an SVD?

$$\textcircled{1} \quad B = Q^T A \in \mathbb{R}^{k \times h}$$

$$\textcircled{2} \quad B = \bar{U} \Sigma V^T \quad \bar{U} \in \mathbb{R}^{k \times k}$$

$$\textcircled{3} \quad A \approx Q Q^T A = QB = \underbrace{Q \bar{U}}_U \Sigma V^T \quad \wedge \quad U = Q \bar{U}$$

Complexities: $A \in \mathbb{R}^{n \times h}$ $Q \in \mathbb{R}^{n \times k}$

$$\textcircled{1} \quad k N^2$$

$$\textcircled{2} \quad k^2 N$$

$$\textcircled{3} \quad k^2 N$$

Finding an LRA basis

How would we *find* an LRA basis?

① Using the SVD (...)

② use a different way?

↳ need a way to make err-rank
tradeoff

- "fixed-rank"
- adaptive.

Giving up optimality

What problem should we actually solve then?

$$\|A - QQ^T A\|_2 \approx \min_{\text{rank}(X) \leq k} \|A - X\|_2$$

where $Q \in \mathbb{R}^{n \times (k+p)}$

p is the "unnecessary"
extra rank.

Recap: The Power Method

How did the power method work again?

A square eigenvalues;
diagonalizable

$$|\lambda_1| \geq |\lambda_2| \geq \dots \geq |\lambda_n| \geq 0 \quad A \vec{y}_i = \lambda_i \vec{y}_i$$

$\vec{x}_0 \in \mathbb{R}^n$ random

$$\vec{x}_0 = \alpha_1 \vec{y}_1 + \dots + \alpha_n \vec{y}_n$$

$$A^q \vec{x}_0 \rightarrow \frac{A^q \vec{x}_0}{\lambda_1^q} = \alpha_1 \frac{\lambda_1^q \vec{y}_1}{\lambda_1^q} + \alpha_2 \frac{\lambda_2^q \vec{y}_2}{\left(\frac{\lambda_1^q}{\lambda_2^q}\right)} + \dots$$

$\in 1$

How do we construct the LRA basis?

Put randomness to work:

① Draw an $n \times \ell$ Gaussian iid random matrix Ω

② $Y = A\Omega$

③

$Y = Q\Omega$

↑
orth. $\in \mathbb{R}^{n \times \ell}$

want: more
power

Tweaking the Range Finder (I)

Can we accelerate convergence?

$$Y = (AA^T)^h A$$

$$A = U\Sigma V^T$$

$$Y = (U\Sigma V^T V\Sigma U^T)^h U\Sigma V^T$$

$$\sigma_i(AA^T A) = \sigma_i(A)^3$$

Tweaking the Range Finder (II)

What is one possible issue with the power method?

- overflow \rightarrow normalize
- non-orth \rightarrow orthogonalize.

Even Faster Matvecs for Range Finding

Assumptions on Ω are pretty weak—can use more or less anything we want.
→ Make it so that we can apply the matvec $A\Omega$ in $O(\cancel{n \log \ell})$ time.
How? Pick Ω as a carefully-chosen subsampling of the Fourier transform.

Errors in Random Approximations

If we use the randomized range finder, how close do we get to the optimal answer?

Theorem

For an $m \times n$ matrix A , a target rank $k \geq 2$ and an oversampling parameter $p \geq 2$ with $k + p \leq \min(m, n)$, with probability $1 - 6 \cdot p^{-p}$,

$$\|A - QQ^T A\|_2 \leq \left(1 + 11\sqrt{k + p\sqrt{\min(m, n)}}\right) \sigma_{k+1}.$$

(given a few more very mild assumptions on p)

[Halko/Tropp/Martinsson '10, 10.3]

Message: We can *probably* (!) get away with oversampling parameters as small as $p = 5$.

A-posteriori and Adaptivity

The result on the previous slide was *a-priori*. Once we're done, can we find out 'how well it turned out'?

$$E = A - QQ^T A$$

$$\|E\|_2 = \sigma_1(E)$$

$\tilde{\omega} \in \mathbb{R}^L$ iid Gaussian

$$\|E\|_2 \approx \max \frac{\|E \tilde{\omega}\|_2}{\|\tilde{\omega}\|_2}$$

Adaptive Range Finding: Algorithm

- ① Compute (small-ish) fixed-rank LRA
- ② Check error
- ③ Add more columns if needed.
